```

Exercise 7.2

Friedman (1991) introduced several benchmark data sets create by simulation. One of these simulations used the following nonlinear equation to create data:

```
y = 10sin(\pi x_1 x_2) + 20(x_3 - 0.5)^2 + 10x_4 + 5x_5 + N(0, \sigma^2)
```

where the x values are random variables uniformly distributed between [0,1] (there are also 5 other non-informative variables also created in the simulation). The package **mlbench** contains a function called mlbench.friedman1 that simulates these data:

(This exercise is based on library(mlbench), which I included in libraries at the top.)

```
set.seed(200)

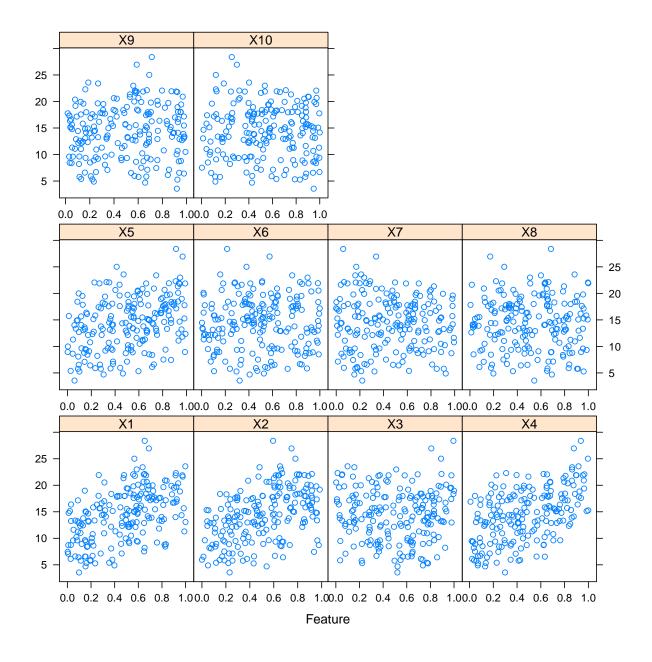

trainingData <- mlbench.friedman1(200, sd = 1)

## We convert the 'x' data from a matrix to a data frame
## One reason is that this will give the columns names.

trainingData$x <- data.frame(trainingData$x)

## Look at the data using

featurePlot(trainingData$x, trainingData$y)</pre>
```

```
## or other methods.
## This creates a list with a vector 'y' and a matrix
## of predictors 'x'. Also simulate a large test set to
## estimate the true error rate with good precision:
testData <- mlbench.friedman1(5000, sd = 1)
testData$x <- data.frame(testData$x)</pre>
Tune several models on these data. For example:
(I included library caret in libraries at the top.)
knnModel <- train(x = trainingData$x, y = trainingData$y, method = "knn", preProc = c("center", "scale"
knnModel
## k-Nearest Neighbors

## RMSE was used to select the optimal model using the smallest value.
## The final value used for the model was k = 17.
knnPred <- predict(knnModel, newdata = testData$x)</pre>
## The function 'postResample' can be used to get the test set
## perforamnce values
postResample(pred = knnPred, obs = testData$y)
##
       RMSE Rsquared
```

Which models appear to give the best performance? Does MARS select the informative predictors (those named X1-X5)?

3.2040595 0.6819919 2.5683461

Answer:

We observed above that the RMSE of kNN model is 3.2932153. In the following, we'll explore all other models, Neural Networks, MARS and SVM, mentioned in the book, in this order.

Neural Networks

Used code from page 163 of textbook.

Warning: executing %dopar% sequentially: no parallel backend registered

Summary

Conclusion

MARS outperformed the others.

Exercise 7.5

Exercise 6.3 describes data for a chemical manufacturing process. Use the same data imputation, data splitting, and pre-processing steps as before and train several nonlinear regression models.

Answer:

Before we begin answring the questions, let's pre-process the data. In previous Homework 7, this data had to be imputed and Box-coxed. I'll do the same this time, but will not inspect with histograms, because we already know about that.

```
data(ChemicalManufacturingProcess)

## [1] 176 58

I'll impute the data using the same technique i.e. mice().

data_imputed <- mice(ChemicalManufacturingProcess, m = 1, method = "pmm", print = F) %>% complete()

## Warning: Number of logged events: 135

any(is.na(data_imputed))

## [1] FALSE
```

At this point, the data is imputed. I'll proceed to Box-Cox it.

```
# Initially identifying columns, whose skewness are not less than 1.
transform_cols <- c()

for(i in seq(from = 1, to = length(data_imputed), by = 1)) {
    if(abs(skewness(data_imputed[, i])) >= 1) {
        transform_cols <- append(transform_cols, names(data_imputed[i]))
    }
}

# Applying Box-cox.
lambda <- NULL
data_imputed_2 <- data_imputed

for (i in 1:length(transform_cols)) {
    lambda[transform_cols[i]] <- BoxCox.lambda(abs(data_imputed[, transform_cols[i]]))

    data_imputed_2[c(transform_cols[i])] <- BoxCox(data_imputed[transform_cols[i]], lambda[transform_cols[i]])</pre>
```

At this point, the data is pre-processed. The pre-processed data is stored in the variable data_imputed_2. So, I'll proceed to split the data into train and test in 80/20 ratio.

```
set.seed(200)

split_index <- createDataPartition(data_imputed_2$Yield, p = 0.8, list = FALSE)

X_train <- data_imputed_2[split_index, ]
y_train <- data_imputed_2$Yield[split_index]

X_test <- data_imputed_2[-split_index, ]
y_test <- data_imputed_2$Yield[-split_index]</pre>
```

(a) Which nonlinear regression model gives the optimal resampling and test set performance?

kNN

```
knnModel <- train(x = X_train, y = y_train, method = "knn", preProc = c("center", "scale"), tuneLength
knnModel

## BiologicalMaterial03
                             21.02
```

In nonlinear models, MARS performed best. The RMSE was very close to zero. But PLS_MODEL, which is linear, returned an RMSE of 0.1308365 is higher than MARS's RMSE. So, it faired worse.

However, in linear model PLS_MODEL, among the top 10 variables, ManufacturingProcess is dominant.

(c) Explore the relationships between the top predictors and the response for the predictors that are unique to the optimal nonlinear regression model. Do these plots reveal intuition about the biological or process predictors and their relationship with yield?

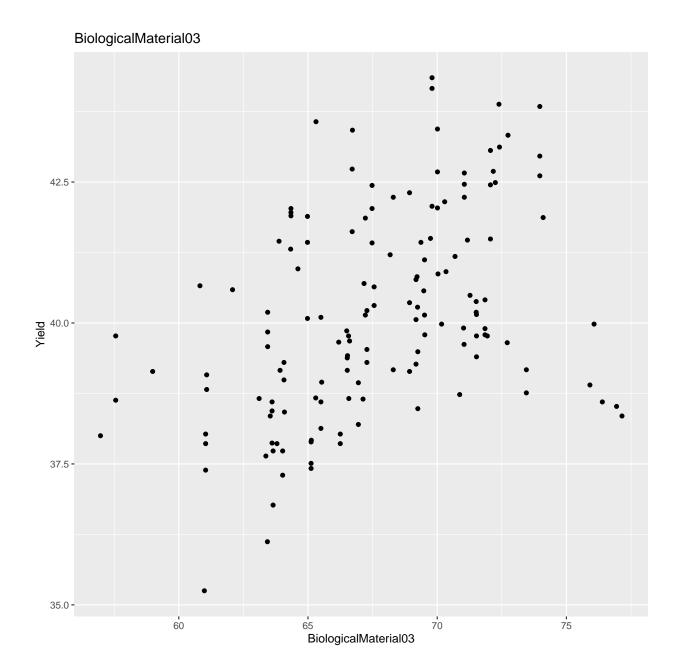

By comparing 20 varImp(nnetTune) with 20 varImp(pls_model), the former being nonlinear and latter liner, we get the following predictors as unique to nonlinear.

BiologicalMaterial03 BiologicalMaterial09 ManufacturingProcess11 ManufacturingProcess30

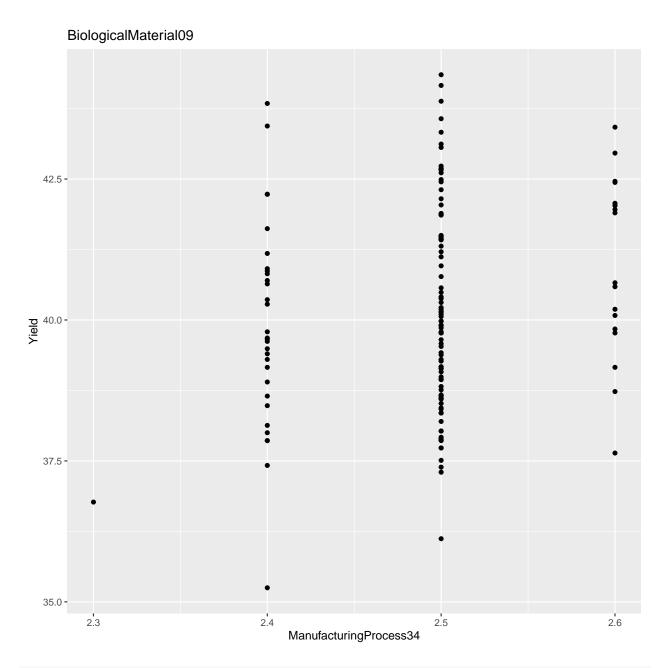

This was done offline manually on Bash-shell.

The plots of each of these variables that are unique to nonlinear set are shown below.

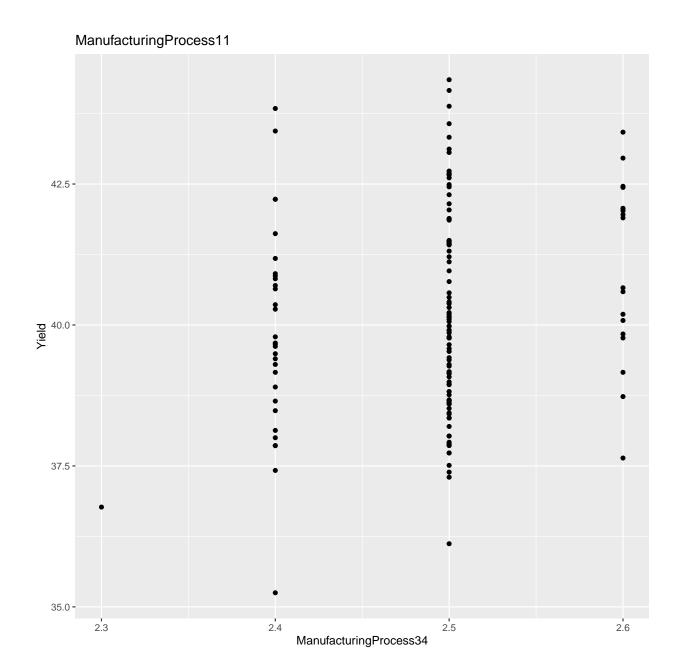

```
ggplot(X_train, aes(BiologicalMaterial03, Yield)) + geom_point() + ggtitle("BiologicalMaterial03")
```

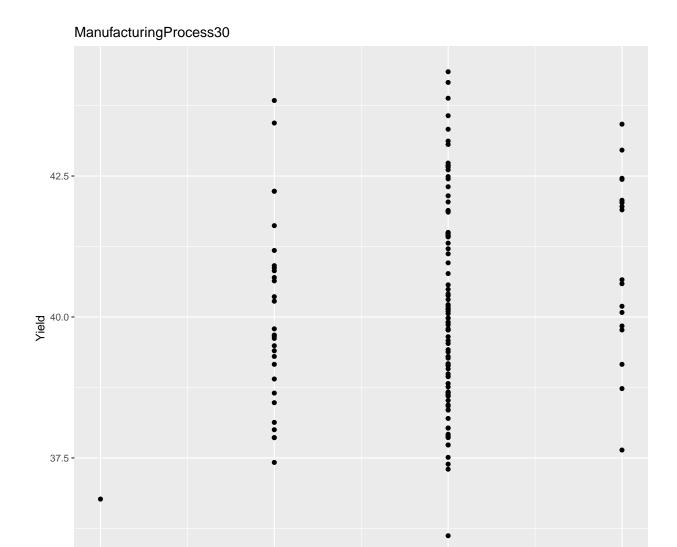

ggplot(X_train, aes(ManufacturingProcess34, Yield)) + geom_point() + ggtitle("BiologicalMaterial09")

ggplot(X_train, aes(ManufacturingProcess34, Yield)) + geom_point() + ggtitle("ManufacturingProcess11")

ggplot(X_train, aes(ManufacturingProcess34, Yield)) + geom_point() + ggtitle("ManufacturingProcess30")

These don't indicate any special relationship.
